ACKNOWLEDGEMENTS

With all praised to Allah S.W.T and the prophet Muhammad S.A.W, I would like to extend my greatest gratitude and deepest appreciation for those who had sincerely without hesitation helped me to finish up my final year project thesis on time with a possible success.

First and foremost, I would like to take this opportunity to express my appreciation and thanks to my supervisor, Madam Wahizatul Afzan Azmi, for her willingness and continuous guidance, tolerance, and encouragement throughout the completion of this project. I also kindly thank to Mr. Amirrudin Ahmad for his helpful support for consenting to the success of this project.

Special thanks dedicated to laboratory assistance in General Biology Laboratory, Mr. Syed Ahmad Rizal Tuan Nek for helping me and Tuan Haji Muhammad Razali Salam who has guided me to identify plant species throughout the sampling period. To Dr. Chuah Tse Seng, thank you for guiding me to conduct the statistical analysis.

Last but not least a big thank you to my lovely mother and large number of friends especially Norsaliza Usali, Roziatul Zaila Bukhari @ Bukari, Che ku Akmar Che ku Othman and everyone else who had indirectly aided me to complete this project, besides encouraged and inspired me that proved to be vital in the successful completion of this endeavor.

ABSTRACT

Butterfly has been identified as important ecological indicator organisms for assessing biodiversity and for monitoring ecosystem responses to environment. This study was conducted to determine the abundance and diversity of butterfly communities and to investigate the interaction between the butterfly species with microhabitats preference in Sungai Tersat, Hulu Terengganu. It was carried out within four months, from August until November 2006. Three stations were selected and butterflies were captured randomly by using insect net. A total of 110 butterflies comprising of 40 species from five families were recorded. The most dominant family with the highest number of individuals was Pieridae (53 individuals). However, Nymphalidae contributed the highest number of species (20 species) at all stations. *Leptosia nina* was the most dominant species collected (25.45%), followed by *Eurema lacteola* (10.91%) and *Ypthima baldus* (8.18%). *Leptosia nina* was mostly occurred in riparian area and they were feeble in flight. Riparian area was microhabitat preferred by most of the butterflies. There was strongly significant correlation between relative humidity to the assemblage of this community. The capture rate varied within sampling months due to climate and seasonal changes. High capture yielded in riparian area where offered heterogeneity of vegetation sites. Less number of individuals was captured in this study site due to human activity such as agriculture and small scale farms. However, in consideration of potential bias and weakness of insect net, it is suggested further sampling with proper condition include a wide variety of techniques to gain a better insight to the butterfly communities along this river.

KELIMPAHAN DAN KEPELBAGAIAN KOMUNITI KUPU-KUPU (ORDER: LEPIDOPTERA) DI SUNGAI TERSAT, HULU TERENGGANU, TERENGGANU

ABSTRAK

Kupu-kupu telah dikenalpasti sebagai organisma penunjuk ekologi untuk menilai biodiversiti dan untuk mengawasi tindak balas ekosistem terhadap alam sekitar. Kajian ini telah dijalankan untuk menentukan kelimpahan dan kepelbagaian komuniti kupu-kupu dan untuk menyiasat interaksi di antara spesies kupu-kupu dengan mikrohabitat pilihan di Sungai Tersat, Hulu Terengganu. Ia dijalankan selama empat bulan bermula dari Ogos sehingga November 2006. Tiga stesen telah dipilih dan kupu-kupu ditangkap secara rawak dengan menggunakan jaring serangga. Sebanyak 110 ekor kupu-kupu yang terdiri daripada 40 spesies daripada lima famili telah direkodkan. Famili paling dominan dengan bilangan individu tertinggi adalah Pieridae (53 individu). Walau bagaimanapun, Nymphalidae menyumbang bilangan spesies tertinggi (20 spesies) di setiap stesen. *Leptosia nina* merupakan spesies dominan yang didapati (25.45%), diikuti oleh *Eurema lacteola* (10.91%), dan *Ypthima baldus* (8.18%). *Leptosia nina* kebanyakannya terdapat di kawasan riparian dan daya terbang mereka adalah lemah. Kawasan riparian adalah mikrohabitat yang dipilih oleh kebanyakan kupu-kupu. Terdapat korelasi signifikan yang kuat di antara kelembapan relatif terhadap perkumpulan komuniti ini. Kadar tangkapan berbeza pada setiap bulan di sebabkan oleh perubahan musim dan iklim. Tangkapan yang tinggi diperolehi di kawasan riparian di mana menawarkan pelbagai tapak vegetasi. Kekurangan bilangan individu yang ditangkap di kawasan kajian ini adalah di sebabkan oleh aktiviti manusia seperti agrikultur dan penternakan kecil-kecilan. Namun, disebabkan persampelan dengan jaring serangga mempunyai ralat dan kelemahan, kajian lanjut perlu dijalankan dalam keadaan cuaca yang lebih sesuai termasuk pelbagai teknik untuk mendapatkan gambaran yang lebih baik terhadap komuniti rama-rama di sepanjang sungai ini.
