## **ACKNOWLEDGEMENT**

First of all, I would like to thank to the God for his blessing in giving me a good health and also opportunity in producing a successful final year project. A thousand thanks also to my both supervisors En. Yusri Yusuf and En. Amirrudin Ahmad, and not to forget my coordinator, Dr. Juanita Joseph for all their advices, helps, supports, guidance and meaningful comments throughout the project.

Special thanks to Dr. Sabri Ahmad and Dr. Md. Lazim for their expert help in the biostatistical analysis, especially in using and interpreting data from the SPSS version 11.5.

I would like to thank the staff of the UMT, particularly En. Sainol, En. Baharim, En. Rashid, En. Shukri, En. ‘Merang’, and Syahnon (The Chef) for their help and guidance during the sampling trips to Pulau Bidong. Appreciation is also to the Librarians of the Sultanah Nur Zahirah Library, in their hard work in helping me to find the specific information for my study.

Besides that, I am deeply grateful to my beloved family and friends (especially Noor Dalila Johar and Siti Shazlina) for their support and encouragement throughout my life as a student. Last but not least, my strongly gratitude to all the members who are involved direct and indirectly throughout the processes of implementing the final year project. All the great memories and hard work is well remembered and appreciated.

## ABSTRACT

The study was conducted at Pulau Bidong, Terengganu, which was one of the unprotected coral areas in the east coast of peninsular Malaysia. The study sites were focused at the areas in front of the island, where three transect lines were set up at different depths. Six sets of temporal variations were used for this study to see the effect of time and grouper abundances. Line intercept transect and fish belt transect were the two main methods used in this study. Four groupers species, from two genera, were observed during the study period. The species observed were *Cephalopholis boenak*, *Cephalopholis cyanostigma*, *Cephalopholis microprion* and *Epinephelus fasciatus*. *C. boenak* and *C. cyanostigma* were the most dominant species and they were found at all sites but were highest at middle and slope areas, and *E. fasciatus* was the least abundant species observed. In this study, significant difference was observed for number of individual groupers and sites ( $P<0.05$ ), with an exception for *E. fasciatus*, but there was no significant difference ( $P>0.05$ ) for the number of groupers and time for temporal variation study. Based on the Pearson correlation coefficient analysis, the mean number of groupers (ind./ $500\text{m}^2$ ) for each site was not significantly correlated to the coral complexity ( $P>0.05$ ). This analysis indicated that the coral complexity did not give any effect to the number of groupers at Pulau Bidong.

# Kajian Terhadap Variasi Ruang Dan Masa Ke Atas Ikan Kerapu

(Famili Serranidae) di Pulau Bidong

## ABSTRAK

Kajian ini dijalankan di Pulau Bidong, Terengganu, yang mana merupakan salah satu kawasan terumbu karang yang tidak dilindungi di pantai timur semenanjung Malaysia. Tempat kajian adalah tertumpu di kawasan hadapan pulau, di mana tiga “transect line” diletakkan di kedalaman yang berbeza. Enam set variasi masa digunakan untuk kajian ini bagi melihat kesan masa dan kelimpahan ikan kerapu. “Line intercept transect” dan “fish belt transect” adalah merupakan dua kaedah utama yang digunakan dalam kajian ini. Empat spesies ikan kerapu daripada dua genus dilihat dalam tempoh kajian dijalankan. Spesies tersebut adalah *Cephalopholis boenak*, *Cephalopholis cyanostigma*, *Cephalopholis microprion* dan *Epinephelus fasciatus*. *C. boenak* dan *C. cyanostigma* adalah merupakan spesies dominan dan dijumpai di kesemua kawasan kajian, tetapi tertinggi di kawasan “middle” dan “slope”, dan *E. fasciatus* merupakan kelimpahan ikan kerapu terendah. Dalam kajian ini, perbezaan secara bererti ( $P<0.05$ ) dilihat untuk bilangan individu ikan kerapu dan tempat kajian, kecuali bagi *E. fasciatus*, dan tiada perbezaan secara bererti ( $P>0.05$ ) untuk bilangan ikan kerapu serta masa bagi kajian variasi masa. Berdasarkan analisis korelasi berpangkat Pearson, didapati bahawa kekompleksan terumbu karang tidak berkorelasi secara bererti ( $P>0.05$ ) dengan purata ikan kerapu ( $\text{ind./}500\text{m}^2$ ) untuk setiap tempat kajian. Ini menunjukkan bahawa kekompleksan terumbu karang tidak mempengaruhi bilangan ikan kerapu di Pulau Bidong.
